Mitsubishi Electric HVICs contribute to the high reliability of various power supply equipment by equipping them with various the protection functions.

High-voltage integrated circuits (HVICs) are capable of directly driving the gates of power MOSFETs and IGBTs using signals input from microcomputers, thereby replacing power MOSFET and IGBT gate drivers that use pulse transformers and photocouplers. They are insulated by a level shift circuit inside the semiconductor chip. Since a variety of protection functions, such as power supply undervoltage, interlocking, input signal filter, and error output, are built into the IC, reliability of the power supply equipment is enhanced.

Mitsubishi Electric has many half-bridge products that are commonly used in drive circuits. Our HVIC products comply with the European Union’s Restriction of Hazardous Substances Directive for electrical equipment, 2011/65/EU and 2015/863/EU.

Innovative Power Devices for a Sustainable Future

- General-purpose inverters
- AC servo/DC brushless motors
- Fluorescent lights/HID lighting/LED lighting
- Voltage translator
- Induction heating cooking stoves
- Air conditioners/Washing machines
- Induction heating cooking stoves
- General-purpose inverters
**1200V HVIC with Desaturation Detection for Power Semiconductors M81748FP**

M81748FP achieves the high durability of 1200V that is most suitable for AC400V inverter systems.

- **High durable 1200V rating that is applicable to an industrial use like AC400V inverter systems**
  - The HVIC achieves low leakage current limited to a maximum 10uA of HVIC by applying a 1200V divided RESURF\(^1\) structure to optimize its surface structure.
  - PolyRFP\(^2\) structure of chip surface greatly enhances the durability.

- **High tolerance to switching noise helps achieve highly reliable inverter systems**
  - High latch-up immunity (parasitic Vertical -PNP transistor action) realized with chip’s low-impedance buried layers.

- **Desaturation detection for reduced power loss reduction in power semiconductors**
  - P-side and N-side desaturation detection prevents overcurrent thermal destruction of the power semiconductors by using 1200V P-channel MOSFET.
  - The HVIC directly detects shorts and earth f Ward faults in power semiconductors on P-side and transmits fault signals to N-side, shutting down systems.
  - Desaturation detection is superior to the detection method which is used the shunt resistor for the power loss reduction in power semiconductors.

**600V HVIC for Automotive Applications M81745JFP**

M81745JFP contributes to the high reliability and the optimized switching control of the voltage converter and the power semiconductor for automotive applications.

- **High reliability that is applied to the requirement of automotive application**
  - Operating temperature range of -40 to +125°C.
  - UVLO (Under voltage lockout) circuit prevents power semiconductor from the destruction by the power supply voltage drop.
  - High-temperature and long-term burn-in tests assure high reliability.
  - The HVIC contributes to the downsizing of the voltage converter by reducing the peripheral parts like the comparator and photocouplers in inverter system.

- **High performance supports effective control of the voltage converters**
  - The HVIC achieves low leakage current limited to a maximum 1uA of HVIC by applying a 600V divided RESURF structure to optimize its surface structure.
  - Easy to control the power semiconductors by matching the delay time of the high-voltage side and low-voltage side.

Attention points of HVIC use

1 The floating power supply method

The emitter/source potential of high-side IGBT/MOSFET referenced to GND changes to the voltage of the HV terminal from 0V when operating the application. Therefore, to drive high-side IGBT/MOSFET, the power supply of the high-side drive circuit of HVIC should have potential which is higher by VBS than the emitter/source potential of high-side IGBT/MOSFET. One of the methods to apply this voltage is the floating power supply method. Fig. right shows the example of the floating power supply method.

2 Bootstrap circuit method and basic operation

Bootstrap circuit method is used in place of the floating power supply method. The bootstrap capacitor(C1) is charged through the resistor (R1) and bootstrap diode(D1) by VCC, and the high-side drive circuit of HVIC is driven by the voltage of the capacitor(C1). Fig. right shows the example of the bootstrap circuit method.

3 Electrical charge and discharge current route when HVIC is operated

Fig. right shows the electrical charge and discharge current route of C1 when HVIC is regularly operated.

Setting of bootstrap capacitor (C1)

To drive high-side MOSFET, the bootstrap capacitor is charged by turning on the resistor (R1) and bootstrap diode(D1) by VCC, and the high-side drive circuit of HVIC is driven by the voltage of the capacitor(C1). Fig. right shows the example of the bootstrap circuit method.

BC1 is shown below. (VC:Voltage between D1 terminals, VDS:Voltage between drain and source of low-side MOSFET)

 VC1=VCC-VF-VDS ・・・ (1)

Simple calculation of bootstrap capacitor (C1)

The capacitance value C1 is shown below. (T1:Maximum on-time of high-side MOSFET, IBS:High-side drive circuit consumption current of HVIC, ΔV:Electrical discharge allowance voltage between C1 terminals)

 C1 = IBS × T1 / ΔV + margin ・・・ (2)

IBS changes depending on gate capacitance of MOSFET and carrier frequency. And (1) and (2) expression are simplified. So please set the capacitance value C1 based on evaluation of your system.
